

Heatmaps of local K-S diagnostics for residual Gaussianity in slice 16. The three rows correspond to nominal Gaussian noise levels of $\sigma = 2, 5$, and 10 , respectively. Each voxel displays $-\log_{10}[\text{mean}_t\{p_{KS}(v, t)\}]$. The color bar is labeled $-\log_{10} p$, and the reference threshold is $-\log_{10}(0.05)$. Values above this threshold correspond to a temporally averaged p value below 0.05 , whereas the remaining values indicate insufficient evidence to reject Gaussianity under this descriptive summary. The displayed values are not additionally truncated. Gray regions in the VSTSUS results denote boundary locations that were not processed because of the preset kernel size and therefore contain NaN values.
