

Residual statistics at the nominal Gaussian noise level of $\sigma = 5$. **(a)** Profiles extracted from Fig.2(h)-(n) along the three-dimensional spatial diagonal from voxel (1,1,1) to (H, W, Z) . The horizontal axis denotes the voxel index along the path, and the vertical axis denotes the residual temporal standard deviation. MSE and r denote the mean squared error and Pearson correlation coefficient, respectively, between each method-specific profile and the known-noise reference profile. **(b)** At each time point, the absolute difference between the number of foreground voxels for which there was insufficient evidence to reject Gaussianity for each method and the corresponding known-noise reference count. The horizontal axis denotes the time point, and the vertical axis denotes the absolute voxel-count difference. $|\Delta\text{Mean}|$ in the legend denotes the absolute difference between the temporal mean count for each method and that of the known-noise reference. Here, r denotes the Pearson correlation coefficient between the corresponding method-specific and known-noise voxel-count trajectories.
